Unit 1

Lesson 3: Graphical method for solving LPP.

Learning outcome

1. Finding the graphical solution to the linear programming model

Graphical Method of solving Linear Programming Problems

Introduction

Dear students, during the preceding lectures, we have learnt how to formulate a given problem as a Linear Programming model.

The next step, after the formulation, is to devise effective methods to solve the model and ascertain the optimal solution.

Dear friends, we start with the graphical method and once having mastered the same, would subsequently move on to simplex algorithm for solving the Linear Programming model.
But let’s not get carried away.

First thing first.
Here we go.

We seek to understand the IMPORTANCE OF GRAPHICAL METHOD OF SOLUTION IN LINEAR PROGRAMMING and seek to find out as to how the graphical method of solution be used to generate optimal solution to a Linear Programming problem.

Once the Linear programming model has been formulated on the basis of the given objective & the associated constraint functions, the next step is to solve the problem & obtain the best possible or the optimal solution various mathematical & analytical techniques can be employed for solving the Linear-programming model.

The graphic solution procedure is one of the method of solving two variable Linear programming problems. It consists of the following steps:-
Step I

Defining the problem. Formulate the problem mathematically. Express it in terms of several mathematical constraints & an objective function. The objective function relates to the optimization aspect is, maximisation or minimisation Criterion.

Step II

Plot the constraints Graphically. Each inequality in the constraint equation has to be treated as an equation. An arbitrary value is assigned to one variable & the value of the other variable is obtained by solving the equation. In the similar manner, a different arbitrary value is again assigned to the variable & the corresponding value of other variable is easily obtained.

These 2 sets of values are now plotted on a graph and connected by a straight line. The same procedure has to be repeated for all the constraints. Hence, the total straight lines would be equal to the total no of equations, each straight line representing one constraint equation.

Step III

Locate the solution space. Solution space or the feasible region is the graphical area which satisfies all the constraints at the same time. Such a solution point \((x, y)\) always occurs at the comer. points of the feasible Region the feasible region is determined as follows:

(a) For "greater than" & "greater than or equal to" constraints (i.e.;), the feasible region or the solution space is the area that lies above the constraint lines.

(b) For "Less Then" &" Less than or equal to" constraint (ie; ). The feasible region or the solution space is the area that lies below the constraint lines.

Step IV

Selecting the graphic technique. Select the appropriate graphic technique to be used for generating the solution. Two techniques viz; Corner Point Method and Iso-profit (or Iso-cost) method may be used, however, it is easier to generate solution by using the corner point method.
Corner Point Method.

(i) Since the solution point \((x, y)\) always occurs at the corner point of the feasible or solution space, identify each of the extreme points or corner points of the feasible region by the method of simultaneous equations.

(ii) By putting the value of the corner point's co-ordinates [e.g. \((2,3)\)] into the objective function, calculate the profit (or the cost) at each of the corner points.

(iii) In a maximisation problem, the optimal solution occurs at that corner point which gives the highest profit.

In a minimisation problem, the optimal solution occurs at that corner point which gives the lowest profit.

Dear students, let us now turn our attention to the important theorems which are used in solving a linear programming problem. Also allow me to explain the important terms used in Linear programming.

Here we go.

**IMPORTANT THEOREMS**

While obtaining the optimum feasible solution to the linear programming problem, the statement of the following four important theorems is used:

**Theorems I.**
The feasible solution space constitutes a convex set.

**Theorems II.**
Within the feasible solution space, feasible solution correspond to the extreme (or Corner) points of the feasible solution space.

**Theorem III.**
There are a finite number of basic feasible solution with the feasible solution space.

**Theorem IV**
The optimum feasible solution, if it exists, will occur at one, or more, of the extreme points that are basic feasible solutions.
Note. Convex set is a polygon "Convex" implies that if any two points of the polygon are selected arbitrarily then straight line segment joining these two points lies completely within the polygon. The extreme points of the convex set are the basic solution to the linear programming problem.

**IMPORTANT TERMS**

Some of the important terms commonly used in linear programming are disclosed as follows:

(i) **Solution**
Values of the decision variable $x_i$ ($i = 1, 2, 3, \text{ in}$) satisfying the constraints of a general linear programming model is known as the solution to that linear programming model.

(ii) **Feasible solution**
Out of the total available solution a solution that also satisfies the non-negativity restrictions of the linear programming problem is called a feasible solution.

(iii) **Basic solution**
For a set of simultaneous equations in $Q$ unknowns ($p Q$) a solution obtained by setting ($P - Q$) of the variables equal to zero & solving the remaining $P$ equation in $P$ unknowns is known as a basic solution.

The variables which take zero values at any solution are detained as non-basic variables & remaining are known as basic variables, often called basic.

(iv) **Basic feasible solution**
A feasible solution to a general linear programming problem which is also basic solution is called a basic feasible solution.

(v) **Optimal feasible solution**
Any basic feasible solution which optimizes (ie; maximise or minimises) the objective function of a linear programming mode known as the optimal feasible solution to that linear programming model.

(vi) **Degenerate Solution**
A basic solution to the system of equations is termed as degenerate if one or more of the basic variables become equal to zero.

I hope the concepts that we have so far discussed have been fully understood by all of you.
Friends, it is now the time to supplement our understanding with the help of examples.

Example 1.

X Ltd wishes to purchase a maximum of 3600 units of a product two types of product a. & b are available in the market. Product a occupies a space of 3 cubic feet & cost Rs. 9 whereas b occupies a space of 1 cubic feet & cost Rs. 13 per unit. The budgetary constraints of the company do not allow to spend more than Rs. 39,000. The total availability of space in the company's godown is 6000 cubic feet. Profit margin of both the product a & b is Rs. 3 & Rs. 4 respectively. Formulate as a linear programming model and solve using graphical method. You are required to ascertain the best possible combination of purchase of a & b so that the total profits are maximized.

Solution

Let \( x_1 = \) no of units of product \( \alpha \) & \( x_2 = \) no of units of product \( \beta \)

Then the problem can be formulated as a P model as follows:

Objective function, Maximise \( Z = 3x_1 + 4x_2 \)

Constraint equations: -
\[
\begin{align*}
 x_1 + x_2 & \leq 3600 \quad (\text{Maximum Units Constraint}) \\
 3x_1 + x_2 & \leq 6000 \quad (\text{Storage area constraint}) \\
 9x_1 + 13x_2 & \leq 39000 \quad (\text{Budgetary constraint}) \\
 x_1 + x_2 & \leq 0
\end{align*}
\]

Step I
Treating all the constraints as equality, the first constraint is
\( x_1 + x_2 = 3600 \)
Put \( x_1 = 0 \Rightarrow x_2 = 3600 \). \( : \) The point is \( (0, 3600) \)
Put \( x_2 = 0 \Rightarrow x_1 = 3600 \). \( : \) The point is \( (3600, 0) \)

Draw is graph with \( x_1 \) on x-axis & \( x_2 \) on y-axis as shown in the figure.
Step II
Determine the set of the points which satisfy the constraint:

\[ x_1 + x_2 = 3600 \]

This can easily be done by verifying whether the origin (0,0) satisfies the constraint. Here, 
\[ 0 + 0 = 3600 \]. Hence all the points below the line will satisfy the constraint.

Step III
The 2\textsuperscript{nd} constraint is: 
\[ 3x_1 + x_2 \leq 6000 \]
Put \( x_1 = 0 \Rightarrow x_2 = 6000 \) and the point is (0, 6000)
Put \( x_2 = 0 \Rightarrow x_1 = 200 \) and the point is (200, 0)
Now draw its graph.

Step IV
Like it’s in the above step II, determine the set of points which satisfy the constraint \( 3x_1 + x_2 \leq 6000 \). At origin; 
\[ 0 + 0 < 6000 \]. Hence, all the points below the line will satisfy the constraint.

Step V
The 3\textsuperscript{rd} constraint is: 
\[ 9x_1 + 12x_2 \leq 39000 \]
Put \( x_1 = 0 \Rightarrow x_2 = 3000 \) & the point is (0, 3000)
Put \( x_2 = 0 \Rightarrow x_1 = \frac{13000}{3} \) & the point is \( \left( \frac{13000}{3}, 0 \right) \)
Now draw its graph.

Step VI
Again the point (0,0) ie; the origin satisfies the constraint \( 9x_1 + 12x_2 \leq 39000 \).
Hence, all the points below the line will satisfy the constraint.

Step VII
The intersection of the above graphic denotes the feasible region for the given problem.
Step VIII

Finding Optimal Solution

Always keep in mind two things:

(i) For ≥ constraint the feasible region will be the area, which lies above the constraint lines, and for ≤ constraints, it will lie below the constraint lines.

This would be useful in identifying the feasible region.

(ii) According to a theorem on linear programming, an optimal solution to a problem (if it exists) is found at a corner point of the solution space.

Step IX

At corner points (O, A, B, C), find the profit value from the objective function. That point which maximize the profit is the optimal point.

<table>
<thead>
<tr>
<th>Corner Point</th>
<th>W-Ordinates</th>
<th>Objective Func</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>O</td>
<td>(0,0)</td>
<td>Z = 3x₁ + 4x₂</td>
<td>0</td>
</tr>
<tr>
<td>A</td>
<td>(0,3000)</td>
<td>Z = 0 + 0</td>
<td>12,000</td>
</tr>
<tr>
<td>C</td>
<td>(2000,0)</td>
<td>Z = 0 + 3x2000 + 0</td>
<td>6,000</td>
</tr>
</tbody>
</table>

For point B, solve the equation \( 9x₁ + 12x₂ ≤ 39000 \)

And \( 3x₁ + 6x₂ ≤ 6000 \) to find point B

(\( ∴ A + B \), these two lines are intersecting)

ie,

\[
\begin{align*}
3x₁ + x₂ &= 6000 \\
9x₁ + x₂ &= 39000
\end{align*}
\]

...(1)

...(2)

Multiply equ (i) by 3 on both sides:
\[9x_1 + 3x_2 = 18000 \quad \ldots (3)\]
\[9x_1 + 13x_2 = 39000 \quad \ldots (4)\]

\[\begin{align*}
-10x_2 &= -21000 \\
\therefore x_2 &= 2100
\end{align*}\]

Put the Value of \(x_2\) in first equation:
\[x_1 = 1300\]
At point (1300,2100)
\[Z = 3x_1 + 4x_2\]
\[= 3 \times 1300 + 4 \times 2100\]
\[= 12,300\] which is the maximum value.

Result
The optimal solution is:
No of units of product \(\alpha = 1300\)
No of units of product \(\beta = 2100\)
Total profit, \(= 12300\) which is the maximum.

Well friends, it's really very simple.
Isn't it?
Let's consider some more examples.

Example 2.

Greatwell Ltd. Produces & sell two different types of products P1 & P2 at a profit margin of Rs. 4 & Rs. 3 respectively. The availability of raw materials the maximum no of production hours available and the limiting factor of P2 can be expressed in terms of the following in equations:

\[\begin{align*}
4x_1 + 2x_2 &\leq 10 \\
2x_1 + \frac{8}{3}x_2 &\leq 8 \\
x_2 &\leq 6 \\
x_1, x_2 &\geq 0
\end{align*}\]

Formulate & solve the LP problem by using graphical method so as to optimize both \(P_1\) & \(P_2\).

Solution
Objective: Maximise \(Z = 4x_1 + 3x_2\)
Since the origin (0,0) satisfies each and every constraint, all points below the line will satisfy the corresponding constraints.

Consider constraints as equations & plot then as under:

\[4x_1 + 2x_2 \leq 10\]

Put \(x_1 = 0 \Rightarrow x = 5\) and the point is (0,5) \(\quad \ldots(1)\)

Put \(x_2 = 0 \Rightarrow x = \frac{5}{2}\) and the point is (5/2, 0)

\[2x_1 + \frac{8}{3}x_2 \leq 8\] \(\quad \ldots(2)\)

Put \(x_1 = 0 \Rightarrow x_2 = 3\) and the point is (, 3)

Put \(x_2 = 0 \Rightarrow x_1 = 4\) and the point is (4, 0)

\[x_1 = 6\] \(\quad \ldots(3)\)

The area under the curve OABC is the solution space. The constraint \(x_1=6\) is not considered since it does not contain the variable \(x_2\).

Getting optimal solution.

<table>
<thead>
<tr>
<th>Corner Point</th>
<th>Co-ordinates</th>
<th>Obj.-Func. [Z = 4x_1 + 3x_2]</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>(0,0)</td>
<td>[Z=0+0] [Z=0+3x3]</td>
<td>0</td>
</tr>
<tr>
<td>A</td>
<td>(0,3)</td>
<td>[\ast] [\ast]</td>
<td>9</td>
</tr>
<tr>
<td>B</td>
<td>(5/2,0)</td>
<td>[Z = 4x_1 \frac{5}{2}x_2 = 8]</td>
<td>10</td>
</tr>
<tr>
<td>C</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Point B is the intersection of the curves \(4x_1 + 2x_2 = 10\) &

\(2x_1 \frac{8}{3}x_2 = 8\)

Solving as system of simultaneous equation:
Point B is (8/5, 9/5)
\[Z = 4x_1 + 3x_2\]
\[= 4(8/5) + 3(9/5) = 59/5\]
Result
The optimal solution is:
Not of units of P2 = 9/5
Total profit = 59/5
Remarks. Since 8/5 & 9/5 units of a product can not be produced, hence these values must be rounded off. This is the limitation of the linear programming technique.

Dear students, we have now reached the end of our discussion scheduled for today.
See you all in the next lecture.
Bye.

Dear students, I hope all of us have by now properly grasped the intricacies involved in the graphical method.

It’s now time to supplement our understanding of the concept by taking various examples.

Here we go.

Example 3.

Due to the unavailability of desired quality of raw materials, ABC Ltd. Can manufacture maximum 80 units of product A & 60 units of product B. A consumes 5 units and B consumes 6 units of raw materials in the manufacture respectively and their respective profit margins one Rs. 50 & Rs. 80.

Further, A requires 1 man-day of labour per unit & B requires 2 man-day of labour per unit. The constraints operating are:

Supply of raw material - maximum 600 units
Supply of labour - maximum 160 man-days.

Formulate as a LP model & solve graphically.
Solution

The question can be presented in a tabular form as under:

<table>
<thead>
<tr>
<th>Product</th>
<th>Raw Material Required</th>
<th>Labour Required</th>
<th>Maximum Units Produced</th>
<th>Profit Per Unit</th>
</tr>
</thead>
<tbody>
<tr>
<td>A</td>
<td>5</td>
<td>1</td>
<td>80</td>
<td>50</td>
</tr>
<tr>
<td>B</td>
<td>6</td>
<td>2</td>
<td>60</td>
<td>80</td>
</tr>
</tbody>
</table>

Let \( x_1 \) = number of units of Product A
\( x_2 \) = number of units of Product B

Since the objective of the company is to maximize its profit. Then the model can be stated as follows:

\[
\text{Maximize } Z = 50x_1 + 80x_2
\]

Subject to the linear constraints

\[
x_1 \leq 80 \quad \text{Functional restrictions}
x_2 \leq 60
\]

\[
5x_1 + 6x_2 \leq 600 \quad \text{(Electronic restrictions)}
\]

\[
x_1, 2x_2 \leq 160 \quad \text{(Labour supply)}
\]

\[
x_1, x_2 \geq 0
\]

Step 2

Graph the constraint inequalities

For the problem, \( x_1 \) axis will represent product A and B respectively. Each inequality will be treated as an equality and then their respective intercepts on both the axis can be determined.

For the first two constraints, we have \( x_1 = 80 \) and \( x_2 = 60 \), i.e., draw a graph with production of product A and product B, as shown below in Fig. 2-1 and Fig 2-2.

Since no more than 80 units of \( x_1 \) can be produced and \( x_2 \leq 60 \), it...
follows that
\[ x_1 \leq 80 \text{ or } x_1 < 80 \text{ and } x_2 \leq 60 \text{ or } x_2 < 60 \]

Thus any point on the line (the equality sign) and other points within the shaded area (the less than sign) will satisfy as shown in Fig. 2-3

Now consider the inequality \( 5x_1 + 6x_2 \leq 600 \). Treating it as a equality we have

\[
X_2 = 80 \\
X_2 = 60
\]

\[
5 X_1 + 6 X_2 = 600 \\
\text{or} \quad X_1 \frac{(600)}{5} + X_2 \frac{(600)}{6} = 1
\]

\[
\text{or} \quad X_1 \frac{200}{1} + X_2 \frac{100}{1} = 1
\]

draw a straight line by joining 120 on \( X_1 \) axis and 100 on \( X_2 \) axis (as shown in fig 2-4) thus the set of points satisfying \( X_1 \geq 0, X_2 \neq 0 \) and the constraint is represented by the shaded area as shown below:
similarly we can draw a graph for $X_1 + 2X_2 \leq 160$

when all the constraint are imposed together, the value of $X_1$ and $X_2$ can lie only in the shaded area. The area which is bounded by all the constraints lines including all the boundary points is called the feasible region or solution space. This is shown in fig 2-5 by the shaded area OABCDE.

**Step 3**

**Locate the solution point**
Since the value of $X_1$ and $X_2$ have to lie in the shaded area which contains an infinite number of points would satisfy the constrains of the virgin L>P>P but we are confined only to those points which corresponds to corners of solution space. Thus as shown in fig. 2-5 the corner points of feasible region are $O = (0,0)$, $A = (80,0)$, $B = (80,33.33)$, $C = (60,50)$, $D = (40,60)$ and $E = (0,60)$

**Step 4**

**Value of objective function at corner points**

<table>
<thead>
<tr>
<th>Corner points</th>
<th>Co-ordinates of corners points $(X_1, X_2)$</th>
<th>Objective $Z = 50X_1 + 80X_2$</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>O</td>
<td>$(0,0)$</td>
<td>$0 + 0$</td>
<td>0</td>
</tr>
<tr>
<td>A</td>
<td>$(80,0)$</td>
<td>$50(80) + 0(0)$</td>
<td>4000</td>
</tr>
<tr>
<td>B</td>
<td>$(80,33.33)$</td>
<td>$50(80) + (80,33.33)$</td>
<td>6666.40</td>
</tr>
<tr>
<td>C</td>
<td>$(60,50)$</td>
<td>$50(60) + 80(50)$</td>
<td>7000</td>
</tr>
<tr>
<td>D</td>
<td>$(40,60)$</td>
<td>$50(40) + 80(60)$</td>
<td>6800</td>
</tr>
<tr>
<td>E</td>
<td>$(0,60)$</td>
<td>$50(0) + 80(60)$</td>
<td>4800</td>
</tr>
</tbody>
</table>

**Step 5**

**Optimal value of the objective function.**
Here we see that the maximum profit of Rs. 7000 is obtained at the point C = (60,50) i.e, $X_1 = 60$ and $X_2 = 50$ which together satisfy all the constraints.

Hence to maximize profit, the company must produce 60 units of product A and 50 units of product B.

**Example 4.**

Alpha Ltd. produces two products X and Y each requiring same production capacity. The total installed production capacity is 9 tones per days. Alpha Ltd. is a supplier of Beta Ltd. Which must supply at least 2 tons of X & 3 tons of Y to Beta Ltd. Every day. The production time for X and Y is 20 machine hour per unit & 50 machine hour per unit respectively the daily maximum possible machine hours is 360 profit margin for X & Y is Rs. 80 per ton and Rs. 120 per ton respectively. Formulate as a LP model and use the graphical method of generating the optimal solution for determining the maximum number of units of X & Y, which can be produced by Alpha Limited.

**Solution**

**Objective function**

Maximize (total profit) $Z = 80X_1 + 120X_2$

Subject to the constraints:

$$X_1 + X_2 \leq 9, \; X_1 \geq 2, \; X_2 \geq 3 \; \text{(Supply constraint)}$$

$$20X_1 + 50X_2 \leq 360 \; \text{(Machine hours constraint)}$$

and

$$X_1 \geq 0, \; X_2 \geq 0$$

Where;

$x_1 = \text{Number of units (in tones) of Product X.}$

$x_2 = \text{Number of units (in tones) of Product Y.}$

Now the region of feasible solution shown in the following figure is bounded by the graphs of the Linear equalities:
The corner points of the solution space are:

A(2,6.4), B (3,3) and D(2,3)

The value of the objective function at these corner points can be determined as follows:

<table>
<thead>
<tr>
<th>Corner Points</th>
<th>Co-ordinates of Corner Points (x₁, x₂)</th>
<th>Objective Function Z=80x₁+20x₂</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>A</td>
<td>(2,6.4)</td>
<td>(80(2) +120(6.4)</td>
<td>928</td>
</tr>
<tr>
<td>B</td>
<td>(3,6)</td>
<td>(80(3) +120 (6)</td>
<td>960</td>
</tr>
<tr>
<td>C</td>
<td>(6,3)</td>
<td>(80(6) +120(3)</td>
<td>840</td>
</tr>
<tr>
<td>D</td>
<td>(2,3)</td>
<td>(80(2) +120(3)</td>
<td>520</td>
</tr>
</tbody>
</table>

The maximum profit (value of Z) of Rs. 960 is found at corner point B i.e., x₁=3 and x₂ = 6. Hence the company should produce 3 tonnes of product X and 6 tonnes of product Y in order to achieve a maximum profit of Rs. 960.
Example 5.

Unique Car Ltd. Manufacturers & sells three different types of Cars A, B, & C. These Cars are manufactured at two different plants of the company having different manufacturing capacities. The following details pertaining to the manufacturing process are provided:

<table>
<thead>
<tr>
<th>Manufacturing Plants</th>
<th>Maximum Production (of Cars)</th>
<th>Operating cost of Plants</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>A</td>
<td>B</td>
</tr>
<tr>
<td>1</td>
<td>50</td>
<td>100</td>
</tr>
<tr>
<td>2</td>
<td>60</td>
<td>60</td>
</tr>
<tr>
<td></td>
<td>2500</td>
<td>3000</td>
</tr>
<tr>
<td>Demand (Cards)</td>
<td>2500</td>
<td>3500</td>
</tr>
</tbody>
</table>

Using the graphical method technique of linear programming, find the least number of days of operations per month so as to minimize the total cost of operations at the two plants.

Solution

Let $x_1$ = no-of days plant 1 operates; and

$X_2$ = no-of days plant 2 operates.

The objective of uniques Car Ltd. is to minimize the operating costs of both its plants.

The above problem can be formulated as follows:

Ie; Minimize $Z = 2,500x_1 + 3,500x_2$ ) Objective )
Subject to:

\[ 50x_1 + 60x_2 \geq 2,500 \]
\[ 100x_1 + 60x_2 \geq 3,000 \]
\[ 100x_1 + 200x_2 \geq 7,000 \]

and \( x_1, x_2 \geq 0 \)

Making the graphs of the above constraints:

The solution space lines at the points A, B, C & D Calculating the Optimal solution:

<table>
<thead>
<tr>
<th>Points</th>
<th>Co-ordinates</th>
<th>Objective – func</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>(0,0)</td>
<td>Z=0+0</td>
<td>0</td>
</tr>
<tr>
<td>A</td>
<td>(70,0)</td>
<td>Z=2500x70+0</td>
<td>1,75,000</td>
</tr>
<tr>
<td>B</td>
<td>(20,25)</td>
<td>Z=2500x20+3500x25</td>
<td>1,37,500</td>
</tr>
<tr>
<td>C</td>
<td>(10,33.33)</td>
<td>Z=2500x10+3500x33.33</td>
<td>1,41,655</td>
</tr>
<tr>
<td>D</td>
<td>(0,50)</td>
<td>Z=0+3500x50</td>
<td>1,75,000</td>
</tr>
</tbody>
</table>
Thus, the least monthly operately cost is at the point B. Where x1=20 days, x2=25 days & operating cost = Rs. 1,37,500.

Example 6.

The chemical composition of common (table) salt is sodium chloride (NACL). Free Flow Salts Pvt. Ltd. Must produce 200 kg of salt per day. The two ingredients have the following cost – profile:

Sodium (Na) - Rs. 3 per kg

Chloride (CL) - Rs. 5 per kg

Using Linear programming find the minimum cost of salt assuming that not more than 80 kg of sodium and at least 60 kg of chloride must be used in the production process.

**Solution**

Formulating as a LP model:

Minimise \( Z = 3x + 5y \) (objective)

Subject to:

\[
\begin{align*}
    x + y &= 200 \, (\text{Total 200 kg to be produced per day}) \\
    x &\leq 80 \, (\text{Sodium not to exceed 80 kg}) \\
    y &\geq 60 \, (\text{Chloride to be used at least 60 kg}) \\
    x, y &\geq 0
\end{align*}
\]

Where

\( x \) = Qty of sodium required in the production &

\( y \) = Qty of chloride required in the production.

It is clear from the graph that there is no feasible solution area. It has only one feasible point having the co-ordinates (80,120).
Optimal solution: $x = 80$, $y = 120$, and $z = 3x+80+5x120=840$ Thus, 80 kg of sodium & 120 kg of chloride shall be mixed in the production of salt at a minimum cost of Rs. 840.

Dear students, we have now reached the end of our discussion scheduled for today.
See you all in the next lecture.
Bye.
